New England Power Grid
2015–2016 Profile

A rapid transformation of the region's electric power resource mix is underway.

Sources of Electricity Production

Major shift from oil and coal to natural gas over the past 15 years

The New England states, electric utilities, and others are evaluating potential solutions to address natural gas infrastructure constraints in the region.

Reliability

Existing natural gas pipelines are inadequate to serve growing peak demand for heating and power generation needs in winter.

Gas-fired generators may also use liquefied natural gas (LNG), but LNG deliveries vary, regional LNG storage is limited, and prices are tied to global markets.

Coal and oil resources are essential during winter, but the rapid retirement of these resources will increase the region's dependence on natural gas.

Pricing

Wholesale electricity prices track the price of power plant fuel, which in New England is typically natural gas.

Natural gas pipeline constraints in the winter tend to increase natural gas prices and, in turn, wholesale electricity prices.

Environmental

The transition from coal and oil to natural gas has reduced emissions.

- NOx: 66%
- SO2: 94%
- CO2: 26%

Kilotons 2001–2014

However, when natural gas pipelines are constrained, oil- and coal-fired electricity production rises, driving up emissions.
Electricity Demand
Demand for electricity peaks in the summer; a smaller peak occurs in the winter. Records: 28,100 MW in summer and 22,800 MW in winter.

State-sponsored energy-efficiency (EE) programs are slowing growth in peak demand, and overall demand growth is flat; states are projected to spend $6 billion on EE between 2019 and 2024.

Increased penetration of plug-in electric vehicles will increase demand for electricity.

New England has approximately 31,000 megawatts (MW) of installed electricity generating capacity
The power generation resource mix is transitioning from coal, oil, and nuclear power to natural gas and renewable energy.

Generation Retirements
Coal- and oil-fired power plants make up nearly 30% of the region's electricity generating capacity but tend to be used only during peak demand periods and are retiring rapidly.

- More than 4,200 MW of coal, oil, and nuclear generating capacity has retired or will retire by mid-2019
- Another 6,000 MW of coal- and oil-fired generators are at risk for retirement by 2020

Proposed Generation
Developers have proposed 13,000 MW of new generating resources as of January 2016.

Imported Power
On an annual basis, New England is generally a net importer of electricity via interconnections to neighboring power systems in New York, Quebec, and New Brunswick.

Percentage of net energy from imports that serves New England's annual electricity demand

Merchant transmission companies, electric utilities, and renewable energy developers are proposing several projects to deliver low- or non-carbon-emitting resources into the New England market.

Wind Power
More than 800 MW of wind power is operational in New England.
Developers are proposing more than 4,000 MW of additional wind power, primarily in northern New England and offshore in southern New England.

Additional transmission will be needed to successfully integrate large-scale wind resources in New England.

Solar Power
State policies are promoting development of behind-the-meter distributed resources, specifically solar photovoltaic (PV) resources.

About ISO New England
Created in 1997, ISO New England is the independent, not-for-profit corporation responsible for the reliable operation of New England’s electric power generation and transmission system, overseeing and ensuring the fair administration of the region’s wholesale electricity markets, and managing comprehensive regional electric power planning.
